TITLE

VITRONECTIN RECEPTOR ANTAGONIST PHARMACEUTICALS

FIELD OF THE INVENTION

5 The present invention provides novel pharmaceuticals
useful for the diagnosis and treatment of cancer, methods
of imaging tumors in a patient, and methods of treating
cancer in a patient. The pharmaceuticals are comprised
of a targeting moiety that binds to the vitronectin
10 receptor that is expressed in tumor vasculature, an
optional linking group, and a therapeutically effective
radioisotope or diagnostically effective imageable
moiety. The therapeutically effective radioisotope emits
a gamma ray or alpha particle sufficient to be cytotoxic.
15 The imageable moiety is a gamma ray or positron emitting
radioisotope, a magnetic resonance imaging contrast
agent, an X-ray contrast agent, or an ultrasound contrast
agent.

BACKGROUND OF THE INVENTION

20 Cancer is a major public health concern in the
United States and around the world. It is estimated that
over 1 million new cases of invasive cancer will be
diagnosed in the United States in 1998. The most
25 prevalent forms of the disease are solid tumors of the
lung, breast, prostate, colon and rectum. Cancer is
typically diagnosed by a combination of in vitro tests
and imaging procedures. The imaging procedures include
X-ray computed tomography, magnetic resonance imaging,
30 ultrasound imaging and radionuclide scintigraphy.
Frequently, a contrast agent is administered to the
patient to enhance the image obtained by X-ray CT, MRI
and ultrasound, and the administration of a
radiopharmaceutical that localizes in tumors is required
35 for radionuclide scintigraphy.

Treatment of cancer typically involves the use of external beam radiation therapy and chemotherapy, either alone or in combination, depending on the type and extent of the disease. A number of chemotherapeutic agents are
5 available, but generally they all suffer from a lack of specificity for tumors versus normal tissues, resulting in considerable side-effects. The effectiveness of these treatment modalities is also limited, as evidenced by the high mortality rates for a number of cancer types,
10 especially the more prevalent solid tumor diseases. More effective and specific treatment means continue to be needed.

Despite the variety of imaging procedures available for the diagnosis of cancer, there remains a need for
15 improved methods. In particular, methods that can better differentiate between cancer and other pathologic conditions or benign physiologic abnormalities are needed. One means of achieving this desired improvement would be to administer to the patient a
20 metallopharmaceutical that localizes specifically in the tumor by binding to a receptor expressed only in tumors or expressed to a significantly greater extent in tumors than in other tissue. The location of the metallopharmaceutical could then be detected externally
25 either by its imageable emission in the case of certain radiopharmaceuticals or by its effect on the relaxation rate of water in the immediate vicinity in the case of magnetic resonance imaging contrast agents.

This tumor specific metallopharmaceutical approach
30 can also be used for the treatment of cancer when the metallopharmaceutical is comprised of a particle emitting radioisotope. The radioactive decay of the isotope at the site of the tumor results in sufficient ionizing radiation to be toxic to the tumor cells. The

specificity of this approach for tumors minimizes the amount of normal tissue that is exposed to the cytotoxic agent and thus may provide more effective treatment with fewer side-effects.

5 Previous efforts to achieve these desired improvements in cancer imaging and treatment have centered on the use of radionuclide labeled monoclonal antibodies, antibody fragments and other proteins or polypeptides that bind to tumor cell surface receptors.

10 The specificity of these radiopharmaceuticals is frequently very high, but they suffer from several disadvantages. First, because of their high molecular weight, they are generally cleared from the blood stream very slowly, resulting in a prolonged blood background in

15 the images. Also, due to their molecular weight they do not extravasate readily at the site of the tumor and then only slowly diffuse through the extravascular space to the tumor cell surface. This results in a very limited amount of the radiopharmaceutical reaching the receptors

20 and thus very low signal intensity in imaging and insufficient cytotoxic effect for treatment.

Alternative approaches to cancer imaging and therapy have involved the use of small molecules, such as peptides, that bind to tumor cell surface receptors. An

25 In-111 labeled somatostatin receptor binding peptide, In-111-DTPA-D-Phe¹-octeotide, is in clinical use in many countries for imaging tumors that express the somatostatin receptor (Baker, et al. Life Sci., 1991, 49, 1583-91 and Krenning, et al., Eur. J. Nucl. Med., 1993,

30 20, 716-31). Higher doses of this radiopharmaceutical have been investigated for potential treatment of these types of cancer (Krenning, et al., Digestion, 1996, 57, 57-61). Several groups are investigating the use of Tc-99m labeled analogs of In-111-DTPA-D-Phe¹-octeotide for

imaging and Re-186 labeled analogs for therapy (Flanagan, et al., U.S. 5,556,939, Lyle, et al., U.S. 5,382,654, and Albert et al., U.S. 5,650,134).

Angiogenesis is the process by which new blood
5 vessels are formed from pre-existing capillaries or post
capillary venules; it is an important component of a
variety of physiological processes including ovulation,
embryonic development, wound repair, and collateral
vascular generation in the myocardium. It is also
10 central to a number of pathological conditions such as
tumor growth and metastasis, diabetic retinopathy, and
macular degeneration. The process begins with the
activation of existing vascular endothelial cells in
response to a variety of cytokines and growth factors.
15 Tumor released cytokines or angiogenic factors stimulate
vascular endothelial cells by interacting with specific
cell surface receptors for the factors. The activated
endothelial cells secrete enzymes that degrade the
basement membrane of the vessels. The endothelial cells
20 then proliferate and invade into the tumor tissue. The
endothelial cells differentiate to form lumens, making
new vessel offshoots of pre-existing vessels. The new
blood vessels then provide nutrients to the tumor
permitting further growth and a route for metastasis.
25 Under normal conditions, endothelial cell
proliferation is a very slow process, but it increases
for a short period of time during embryogenesis,
ovulation and wound healing. This temporary increase in
cell turnover is governed by a combination of a number of
30 growth stimulatory factors and growth suppressing
factors. In pathological angiogenesis, this normal
balance is disrupted resulting in continued increased
endothelial cell proliferation. Some of the
proangiogenic factors that have been identified include

basic fibroblast growth factor (bFGF), angiogenin, TGF-alpha, TGF-beta, and vascular endothelium growth factor (VEGF). While interferon-alpha, interferon-beta and thrombospondin are examples of angiogenesis suppressors.

5 The proliferation and migration of endothelial cells in the extracellular matrix is mediated by interaction with a variety of cell adhesion molecules (Folkman, J., Nature Medicine , 1995, 1, 27-31). Integrins are a diverse family of heterodimeric cell surface receptors by which endothelial cells attach to the extracellular
10 matrix, each other and other cells. The integrin $\alpha_v\beta_3$ is a receptor for a wide variety of extracellular matrix proteins with an exposed tripeptide Arg-Gly-Asp moiety and mediates cellular adhesion to its
15 ligand: vitronectin, fibronectin, and fibrinogen, among others. The integrin $\alpha_v\beta_3$ is minimally expressed on normal blood vessels, but is significantly upregulated on vascular cells within a variety of human tumors. The role of the $\alpha_v\beta_3$ receptors is to mediate the interaction
20 of the endothelial cells and the extracellular matrix and facilitate the migration of the cells in the direction of the angiogenic signal, the tumor cell population. Angiogenesis induced by bFGF or TNF-alpha depend on the agency of the integrin $\alpha_v\beta_3$, while angiogenesis induced
25 by VEGF depends on the integrin $\alpha_v\beta_3$ (Cheresh et. al., Science, 1995, 270, 1500-2). Induction of expression of the integrins $\alpha_1\beta_1$ and $\alpha_2\beta_1$ on the endothelial cell surface is another important mechanism by which VEGF promotes angiogenesis (Senger, et. al., Proc. Natl. Acad,
30 Sci USA, 1997, 84, 13612-7).

Angiogenic factors interact with endothelial cell surface receptors such as the receptor tyrosine kinases EGFR, FGFR, PDGFR, Flk-1/KDR, Flt-1, Tek, tie, neuropilin-1, endoglin, endosialin, and Axl. The
5 receptors Flk-1/KDR, neuropilin-1, and Flt-1 recognize VEGF and these interactions play key roles in VEGF-induced angiogenesis. The Tie subfamily of receptor tyrosine kinases are also expressed prominently during blood vessel formation.

10 Because of the importance of angiogenesis to tumor growth and metastasis, a number of chemotherapeutic approaches are being developed to interfere with or prevent this process. One of these approaches, involves the use of anti-angiogenic proteins such as angiostatin
15 and endostatin. Angiostatin is a 38 kDa fragment of plasminogen that has been shown in animal models to be a potent inhibitor of endothelial cell proliferation. (O'Reilly et. al. , Cell, 1994, 79, 315-328) Endostatin is a 20 kDa C-terminal fragment of collagen XVIII that
20 has also been shown to be a potent inhibitor. (O'Reilly et. al., Cell, 1997, 88, 277-285) Systemic therapy with endostatin has been shown to result in strong anti-tumor activity in animal models. However, human clinical trials of these two chemotherapeutic agents of biological origin
25 have been hampered by lack of availability.

Another approach to anti-angiogenic therapy is to use targeting moieties that interact with endothelial cell surface receptors expressed in the angiogenic vasculature to which are attached chemotherapeutic
30 agents. Burrows and Thorpe (Proc. Nat. Acad. Sci, USA, 1993, 90, 8996-9000) described the use of an antibody-immunotoxin conjugate to eradicate tumors in a mouse model by destroying the tumor vasculature. The antibody was raised against an endothelial cell class II antigen

of the major histocompatibility complex and was then conjugated with the cytotoxic agent, deglycosylated ricin A chain. The same group (Clin. Can. Res., 1995, 1, 1623-1634) investigated the use of antibodies raised against
5 the endothelial cell surface receptor, endoglin, conjugated to deglycosylated ricin A chain. Both of these conjugates exhibited potent anti-tumor activity in mouse models. However, both still suffer drawbacks to routine human use. As with most antibodies or other large,
10 foreign proteins, there is considerable risk of immunologic toxicity which could limit or preclude administration to humans. Also, while the vasculature targeting may improve the local concentration of the attached chemotherapeutic agents, the agents still must
15 be cleaved from the antibody carrier and be transported or diffuse into the cells to be cytotoxic.

Thus, it is desirable to provide anti-angiogenic pharmaceuticals and tumor or new vasculature imaging agents which do not suffer from poor diffusion or
20 transportation, possible immunologic toxicity, limited availability, and/or a lack of specificity.

Another application of anti-angiogenic therapy is in treating rheumatoid arthritis (RA). In RA, the ingrowth of a highly vascularized pannus is caused by the
25 excessive production of angiogenic factors by the infiltrating macrophages, immune cells, or inflammatory cells. Therefore, it is desirable to have new pharmaceuticals to destroy the highly vascularized pannus that results and thus treat the disease.

30 There is also a growing interest in therapeutic angiogenesis to improve blood flow in regions of the body that have become ischemic or poorly perfused. Several investigators are using growth factors administered locally to cause new vasculature to form either in the

limbs or the heart. The growth factors VEGF and bFGF are the most common for this application. Recent publications include: Takeshita, S., et. al., J. Clin. Invest., 1994, 93, 662-670; and Schaper, W. and Schaper, J., Collateral Circulation: Heart, Brain, Kidney, Limbs, Kluwer Academic Publishers, Boston, 1993. The main applications that are under investigation in a number of laboratories are for improving cardiac blood flow and in improving peripheral vessel blood flow in the limbs. For example, Henry, T. et. al. (J. Amer. College Cardiology, 1998, 31, 65A) describe the use of recombinant human VEGF in patients for improving myocardial perfusion by therapeutic angiogenesis. Patients received infusions of rhVEGF and were monitored by nuclear perfusion imaging 30 and 60 days post treatment to determine improvement in myocardial perfusion. About 50% of patients showed improvement by nuclear perfusion imaging whereas 5/7 showed new collateralization by angiography. Thus, it is desirable to discover a method of monitoring improved cardiac blood flow which is targeted to new collateral vessels themselves and not, as in nuclear perfusion imaging, a regional consequence of new collateral vessels.

The detection, imaging and diagnosis of a number of cardiovascular diseases need to be improved, including restenosis, atherosclerosis, myocardial reperfusion injury, and myocardial ischemia, stunning or infarction. It has recently been determined that in all of these disease conditions, the integrin receptor $\alpha v \beta 3$ plays an important role.

For example, in the restenosis complication that occurs in ~30-50% of patients having undergone angioplasty or stent placement, neointimal hyperplasia and ultimate reocclusion is caused by aggressively

proliferating vascular smooth muscle cells that express $\alpha_v\beta_3$. (Cardiovascular Res., 1997, 36, 408-428; DDT, 1997, 2, 187-199; Current Pharm. Design, 1997, 3, 545-584)

5 Atherosclerosis proceeds from an intial endothelial damage that results in the recruitment and subintimal migration of monocytes at the site of the injury. Growth factors are released which induce medial smooth muscle cells to proliferate and migrate to the intimal layer. The migrating smooth muscle cells express $\alpha_v\beta_3$.

10 In reperfusion injury, neutrophil transmigration is integrin dependent and the integrins moderate initial infiltration into the viable border zone. The induction of $\alpha_5\beta_1$, $\alpha_4\beta_1$ and $\alpha_v\beta_5$ in infiltrating neutrophils occurs within 3 to 5 hours after reperfusion as neutrophils move
15 from the border zone to the area of necrosis. (Circulation, 1999, 100, I-275)

Acute or chronic occlusion of a coronary artery is known to result in angiogenesis in the heart as native collateral vessels are recruited to attempt to relieve
20 the ischemia. However, even a gradual occlusion usually results in areas of infarction as the resulting angiogenesis is not sufficient to prevent damage. Cardiac angiogenesis has been associated with increased expression of the growth factors VEGF and FGF and the
25 upregulation of the growth factor receptors flt-1 and flk-1/KDR. (Drugs, 1999, 58, 391-396)

SUMMARY OF THE INVENTION

30 It is one object of the present invention to provide improved anti-angiogenic pharmaceuticals, comprised of a targeting moiety that binds to the vitronectin receptor that is expressed in tumor neovasculature, an optional

linking group, and a radioisotope. The vitronectin receptor binding compounds target the radioisotope to the tumor neovasculature. The beta or alpha-particle emitting radioisotope emits a cytotoxic amount of ionizing radiation which results in cell death. The penetrating ability of radiation obviates the requirement that the cytotoxic agent diffuse or be transported into the cell to be cytotoxic.

It is another object of the present invention to provide pharmaceuticals to treat rheumatoid arthritis. These pharmaceuticals comprise a targeting moiety that binds to a receptor that is upregulated during angiogenesis, an optional linking group, and a radioisotope that emits cytotoxic radiation (i.e., beta particles, alpha particles and Auger or Coster-Kronig electrons). In rheumatoid arthritis, the ingrowth of a highly vascularized pannus is caused by the excessive production of angiogenic factors by the infiltrating macrophages, immune cells, or inflammatory cells. Therefore, the radiopharmaceuticals of the present invention that emit cytotoxic radiation could be used to destroy the new angiogenic vasculature that results and thus treat the disease.

It is another object of the present invention to provide imaging agents, comprised of vitronectin receptor binding compounds conjugated to an imageable moiety, such as a gamma ray or positron emitting radioisotope, a magnetic resonance imaging contrast agent, an X-ray contrast agent, or an ultrasound contrast agent. These imaging agents are useful for imaging tumor neovasculature, therapeutic angiogenesis interventions in the heart, natural angiogenic processes in response to acute or chronic coronary vessel occlusion, restenosis

post-angioplasty, atherosclerosis and plaque formation, and reperfusion injury.

It is another object of the present invention to provide compounds useful for preparing the
5 pharmaceuticals of the present invention. These compounds are comprised of a non-peptide indazole containing targeting moiety that binds to a receptor that is upregulated during angiogenesis or during
10 cardiovascular diseases, Q, an optional linking group, L_n , and a metal chelator or bonding moiety, C_h . The compounds may have one or more protecting groups attached to the metal chelator or bonding moiety. The protecting groups provide improved stability to the reagents for long-term storage and are removed either immediately
15 prior to or concurrent with the synthesis of the radiopharmaceuticals. Alternatively, the compounds of the present invention are comprised of a peptide or peptidomimetic targeting moiety that binds to a receptor that is upregulated during angiogenesis or during
20 cardiovascular diseases, Q, an optional linking group, L_n , and a surfactant, S_f .

The pharmaceuticals of the present invention may be used for diagnostic and/or therapeutic purposes. Diagnostic radiopharmaceuticals of the present invention
25 are pharmaceuticals comprised of a diagnostically useful radionuclide (i.e., a radioactive metal ion that has imageable gamma ray or positron emissions). Therapeutic radiopharmaceuticals of the present invention are pharmaceuticals comprised of a therapeutically useful
30 radionuclide, a radioactive metal ion that emits ionizing radiation such as beta particles, alpha particles and Auger or Coster-Kronig electrons.

The pharmaceuticals comprising a gamma ray or positron emitting radioactive metal ion are useful for

imaging tumors and by gamma scintigraphy or positron emission tomography. The pharmaceuticals comprising a gamma ray or positron emitting radioactive metal ion are also useful for imaging therapeutic angiogenesis, natural
5 angiogenic processes in response to acute or chronic coronary vessel occlusion, restenosis post-angioplasty, atherosclerosis and plaque formation, and reperfusion injury by gamma scintigraphy or positron emission tomography. The pharmaceuticals comprising a particle
10 emitting radioactive metal ion are useful for treating cancer by delivering a cytotoxic dose of radiation to the tumors. The pharmaceuticals comprising a particle emitting radioactive metal ion are also useful for treating rheumatoid arthritis by destroying the formation
15 of angiogenic vasculature. The pharmaceuticals comprising a paramagnetic metal ion are useful as magnetic resonance imaging contrast agents. The pharmaceuticals comprising one or more X-ray absorbing or "heavy" atoms of atomic number 20 or greater are useful
20 as X-ray contrast agents. The pharmaceuticals comprising a microbubble of a biocompatible gas, a liquid carrier, and a surfactant microsphere, are useful as ultrasound contrast agents.

DEFINITIONS

The compounds herein described may have asymmetric centers. Unless otherwise indicated, all chiral, diastereomeric and racemic forms are included in the present invention. Many geometric isomers of olefins, C=N double bonds, and the like can also be present in the compounds described herein, and all such stable isomers are contemplated in the present invention. It will be appreciated that compounds of the present invention contain asymmetrically substituted carbon atoms, and may be isolated in optically active or racemic forms. It is well known in the art how to prepare optically active forms, such as by resolution of racemic forms or by synthesis from optically active starting materials. Two distinct isomers (cis and trans) of the peptide bond are known to occur; both can also be present in the compounds described herein, and all such stable isomers are contemplated in the present invention. The D and L-isomers of a particular amino acid are designated herein using the conventional 3-letter abbreviation of the amino acid, as indicated by the following examples: D-Leu, or L-Leu.

When any variable occurs more than one time in any substituent or in any formula, its definition on each occurrence is independent of its definition at every other occurrence. Thus, for example, if a group is shown to be substituted with 0-2 R⁵², then said group may optionally be substituted with up to two R⁵², and R⁵² at

each occurrence is selected independently from the defined list of possible R^{52} . Also, by way of example, for the group $-N(R^{53})_2$, each of the two R^{53} substituents on N is independently selected from the defined list of possible R^{53} . Combinations of substituents and/or variables are permissible only if such combinations result in stable compounds. When a bond to a substituent is shown to cross the bond connecting two atoms in a ring, then such substituent may be bonded to any atom on the ring.

The term "nonpeptide" means preferably less than three amide bonds in the backbone core of the targeting moiety or preferably less than three amino acids or amino acid mimetics in the targeting moiety.

The term "metallopharmaceutical" means a pharmaceutical comprising a metal. The metal is the cause of the imageable signal in diagnostic applications and the source of the cytotoxic radiation in radiotherapeutic applications. Radiopharmaceuticals are metallopharmaceuticals in which the metal is a radioisotope.

By "reagent" is meant a compound of this invention capable of direct transformation into a metallopharmaceutical of this invention. Reagents may be utilized directly for the preparation of the metallopharmaceuticals of this invention or may be a component in a kit of this invention.

The term "binding agent" means a metallopharmaceutical of this invention having affinity for and capable of binding to the vitronectin receptor. The binding agents of this invention have $K_i < 1000\text{nM}$.

By "stable compound" or "stable structure" is meant herein a compound that is sufficiently robust to survive isolation to a useful degree of purity from a reaction

mixture, and formulation into an efficacious pharmaceutical agent.

The term "substituted", as used herein, means that one or more hydrogens on the designated atom or group is replaced with a selection from the indicated group, provided that the designated atom's or group's normal valency is not exceeded, and that the substitution results in a stable compound. When a substituent is keto (i.e., =O), then 2 hydrogens on the atom are replaced.

The term "bond", as used herein, means either a single or double bond.

The term "salt", as used herein, is used as defined in the CRC Handbook of Chemistry and Physics, 65th Edition, CRC Press, Boca Raton, Fla, 1984, as any substance which yields ions, other than hydrogen or hydroxyl ions. As used herein, "pharmaceutically acceptable salts" refer to derivatives of the disclosed compounds modified by making acid or base salts.

Examples of pharmaceutically acceptable salts include, but are not limited to, mineral or organic acid salts of basic residues such as amines; alkali or organic salts of acidic residues such as carboxylic acids; and the like.

The phrase "pharmaceutically acceptable" is employed herein to refer to those compounds, materials,

compositions, and/or dosage forms which are, within the scope of sound medical judgment, suitable for use in contact with the tissues of human beings and animals without excessive toxicity, irritation, allergic response, or other problem or complication, commensurate with a reasonable benefit/risk ratio.

As used herein, "pharmaceutically acceptable salts" refer to derivatives of the disclosed compounds wherein the parent compound is modified by making acid or base salts thereof. Examples of pharmaceutically acceptable

salts include, but are not limited to, mineral or organic acid salts of basic residues such as amines; alkali or organic salts of acidic residues such as carboxylic acids; and the like. The pharmaceutically acceptable salts include the conventional non-toxic salts or the quaternary ammonium salts of the parent compound formed, for example, from non-toxic inorganic or organic acids. For example, such conventional non-toxic salts include those derived from inorganic acids such as hydrochloric, hydrobromic, sulfuric, sulfamic, phosphoric, nitric and the like; and the salts prepared from organic acids such as acetic, propionic, succinic, glycolic, stearic, lactic, tartaric, citric, ascorbic, pamoic, maleic, hydroxymaleic, phenylacetic, glutamic, benzoic, salicylic, sulfanilic, 2-acetoxybenzoic, fumaric, toluenesulfonic, methanesulfonic, ethane disulfonic, oxalic, isethionic, and the like.

The pharmaceutically acceptable salts of the present invention can be synthesized from the parent compound which contains a basic or acidic moiety by conventional chemical methods. Generally, such salts can be prepared by reacting the free acid or base forms of these compounds with a stoichiometric amount of the appropriate base or acid in water or in an organic solvent, or in a mixture of the two; generally, nonaqueous media like ether, ethyl acetate, ethanol, isopropanol, or acetonitrile are preferred. Lists of suitable salts are found in *Remington's Pharmaceutical Sciences*, 17th ed., Mack Publishing Company, Easton, PA, 1985, p. 1418, the disclosure of which is hereby incorporated by reference.

The formation of the intermediate complex is kinetically favored while the formation of the metallopharmaceutical is thermodynamically favored. Transfer ligands useful in the preparation of metallopharmaceuticals and in diagnostic kits useful for the preparation of diagnostic radiopharmaceuticals include but are not limited to gluconate, glucoheptonate, mannitol, glucarate, N,N,N',N'-ethylenediaminetetraacetic acid, pyrophosphate and methylenediphosphonate. In general, transfer ligands are comprised of oxygen or nitrogen donor atoms.

The term "donor atom" refers to the atom directly attached to a metal by a chemical bond.

"Ancillary" or "co-ligands" are ligands that are incorporated into a radiopharmaceutical during its synthesis. They serve to complete the coordination sphere of the radionuclide together with the chelator or radionuclide bonding unit of the reagent. For radiopharmaceuticals comprised of a binary ligand system, the radionuclide coordination sphere is composed of one

or more chelators or bonding units from one or more reagents and one or more ancillary or co-ligands, provided that there are a total of two types of ligands, chelators or bonding units. For example, a

5 radiopharmaceutical comprised of one chelator or bonding unit from one reagent and two of the same ancillary or co-ligands and a radiopharmaceutical comprised of two chelators or bonding units from one or two reagents and one ancillary or co-ligand are both considered to be

10 comprised of binary ligand systems. For radiopharmaceuticals comprised of a ternary ligand system, the radionuclide coordination sphere is composed of one or more chelators or bonding units from one or more reagents and one or more of two different types of

15 ancillary or co-ligands, provided that there are a total of three types of ligands, chelators or bonding units. For example, a radiopharmaceutical comprised of one chelator or bonding unit from one reagent and two different ancillary or co-ligands is considered to be

20 comprised of a ternary ligand system.

Ancillary or co-ligands useful in the preparation of radiopharmaceuticals and in diagnostic kits useful for the preparation of said radiopharmaceuticals are comprised of one or more oxygen, nitrogen, carbon,

25 sulfur, phosphorus, arsenic, selenium, and tellurium donor atoms. A ligand can be a transfer ligand in the synthesis of a radiopharmaceutical and also serve as an ancillary or co-ligand in another radiopharmaceutical. Whether a ligand is termed a transfer or ancillary or

30 co-ligand depends on whether the ligand remains in the radionuclide coordination sphere in the radiopharmaceutical, which is determined by the coordination chemistry of the radionuclide and the chelator or bonding unit of the reagent or reagents.

A "chelator" or "bonding unit" is the moiety or group on a reagent that binds to a metal ion through the formation of chemical bonds with one or more donor atoms.

The term "binding site" means the site in vivo or
5 in vitro that binds a biologically active molecule.

A "diagnostic kit" or "kit" comprises a collection of components, termed the formulation, in one or more vials which are used by the practicing end user in a clinical or pharmacy setting to synthesize diagnostic
10 radiopharmaceuticals. The kit provides all the requisite components to synthesize and use the diagnostic radiopharmaceutical except those that are commonly available to the practicing end user, such as water or saline for injection, a solution of the radionuclide,
15 equipment for heating the kit during the synthesis of the radiopharmaceutical, if required, equipment necessary for administering the radiopharmaceutical to the patient such as syringes and shielding, and imaging equipment.

Therapeutic radiopharmaceuticals, X-ray contrast
20 agent pharmaceuticals, ultrasound contrast agent pharmaceuticals and metallopharmaceuticals for magnetic resonance imaging contrast are provided to the end user in their final form in a formulation contained typically in one vial, as either a lyophilized solid or an aqueous
25 solution. The end user reconstitutes the lyophilized with water or saline and withdraws the patient dose or just withdraws the dose from the aqueous solution formulation as provided.

A "lyophilization aid" is a component that has
30 favorable physical properties for lyophilization, such as the glass transition temperature, and is added to the formulation to improve the physical properties of the combination of all the components of the formulation for lyophilization.

A "stabilization aid" is a component that is added to the metallopharmaceutical or to the diagnostic kit either to stabilize the metallopharmaceutical or to prolong the shelf-life of the kit before it must be used.

5 Stabilization aids can be antioxidants, reducing agents or radical scavengers and can provide improved stability by reacting preferentially with species that degrade other components or the metallopharmaceutical.

10 A "solubilization aid" is a component that improves the solubility of one or more other components in the medium required for the formulation.

A "bacteriostat" is a component that inhibits the growth of bacteria in a formulation either during its storage before use or after a diagnostic kit is used to
15 synthesize a radiopharmaceutical.

Thus, the lipids may be used to form a unilamellar vesicle (comprised of one monolayer or bilayer), an oligolamellar vesicle (comprised of about two or about three monolayers or bilayers) or a multilamellar vesicle (comprised of more than about three monolayers or bilayers). The internal void of the vesicles may be filled with a liquid, including, for example, an aqueous liquid, a gas, a gaseous precursor, and/or a solid or solute material, including, for example, a bioactive agent, as desired.

As used herein, the term "lipsomes" refers to a generally spherical cluster or aggregate of amphipathic compounds, including lipid compounds, typically in the form of one or more concentric layers, for example, bilayers. They may also be referred to herein as lipid vesicles.

Angiogenesis is the process of formation of new capillary blood vessels from existing vasculature. It is an important component of a variety of physiological

processes including ovulation, embryonic development, wound repair, and collateral vascular generation in the myocardium. It is also central to a number of pathological conditions such as tumor growth and
5 metastasis, diabetic retinopathy, and macular degeneration. The process begins with the activation of existing vascular endothelial cells in response to a variety of cytokines and growth factors. The activated endothelial cells secrete enzymes that degrade the
10 basement membrane of the vessels. The endothelial cells then proliferate and migrate into the extracellular matrix first forming tubules and subsequently new blood vessels.

Under normal conditions, endothelial cell
15 proliferation is a very slow process, but it increases for a short period of time during embryogenesis, ovulation and wound healing. This temporary increase in cell turnover is governed by a combination of a number of growth stimulatory factors and growth suppressing
20 factors. In pathological angiogenesis, this normal balance is disrupted resulting in continued increased endothelial cell proliferation. Some of the pro-angiogenic factors that have been identified include basic fibroblast growth factor (bFGF), angiogenin, TGF-
25 alpha, TGF-beta, and vascular endothelium growth factor (VEGF), while interferon-alpha, interferon-beta and thrombospondin are examples of angiogenesis suppressors.

Angiogenic factors interact with endothelial cell surface receptors such as the receptor tyrosine kinases
30 EGFR, FGFR, PDGFR, Flk-1/KDR, Flt-1, Tek, Tie, neuropilin-1, endoglin, endosialin, and Axl. The receptors Flk-1/KDR, neuropilin-1, and Flt-1 recognize VEGF and these interactions play key roles in VEGF-induced angiogenesis. The Tie subfamily of receptor

tyrosine kinases are also expressed prominently during blood vessel formation.

The proliferation and migration of endothelial cells in the extracellular matrix is mediated by interaction with a variety of cell adhesion molecules. Integrins are a diverse family of heterodimeric cell surface receptors by which endothelial cells attach to the extracellular matrix, each other and other cells. Angiogenesis induced by bFGF or TNF-alpha depend on the agency of the integrin avb3, while angiogenesis induced by VEGF depends on the integrin avb5 (Cheresh et. al., Science, 1995, 270, 1500-2). Induction of expression of the integrins albl and a2b1 on the endothelial cell surface is another important mechanism by which VEGF promotes angiogenesis (Senger, et. al., Proc. Natl. Acad, Sci USA, 1997, 94, 13612-7).

The pharmaceuticals of the present invention are comprised of a non-peptide targeting moiety for the vitronectin receptor that is expressed or upregulated in angiogenic tumor vasculature.

The ultrasound contrast agents of the present invention comprise a plurality of vitronectin receptor targeting moieties attached to or incorporated into a microbubble of a biocompatible gas, a liquid carrier, and a surfactant microsphere, further comprising an optional linking moiety, L_n , between the targeting moieties and the microbubble. In this context, the term liquid carrier means aqueous solution and the term surfactant means any amphiphilic material which produces a reduction in interfacial tension in a solution. A list of suitable surfactants for forming surfactant microspheres is disclosed in EP0727225A2, herein incorporated by reference. The term surfactant microsphere includes nanospheres, liposomes, vesicles and the like. The

biocompatible gas can be air, or a fluorocarbon, such as a C₃-C₅ perfluoroalkane, which provides the difference in echogenicity and thus the contrast in ultrasound imaging. The gas is encapsulated or contained in the microsphere
5 to which is attached the biodirecting group, optionally via a linking group. The attachment can be covalent, ionic or by van der Waals forces. Specific examples of such contrast agents include lipid encapsulated perfluorocarbons with a plurality of tumor neovasculature
10 receptor binding peptides, polypeptides or peptidomimetics.

X-ray contrast agents of the present invention are comprised of one or more vitronectin receptor targeting moieties attached to one or more X-ray absorbing or
15 "heavy" atoms of atomic number 20 or greater, further comprising an optional linking moiety, L_n, between the targeting moieties and the X-ray absorbing atoms. The frequently used heavy atom in X-ray contrast agents is iodine. Recently, X-ray contrast agents comprised of
20 metal chelates (Wallace, R., U.S. 5,417,959) and polychelates comprised of a plurality of metal ions (Love, D., U.S. 5,679,810) have been disclosed. More recently, multinuclear cluster complexes have been disclosed as X-ray contrast agents (U.S. 5,804,161, PCT
25 WO91/14460, and PCT WO 92/17215).

MRI contrast agents of the present invention are comprised of one or more vitronectin receptor targeting moieties attached to one or more paramagnetic metal ions, further comprising an optional linking moiety, L_n,
30 between the targeting moieties and the paramagnetic metal ions. The paramagnetic metal ions are present in the form of metal complexes or metal oxide particles. U.S. 5,412,148, and 5,760,191, describe examples of chelators for paramagnetic metal ions for use in MRI contrast

agents. U.S. 5,801,228, U.S. 5,567,411, and U.S. 5,281,704, describe examples of polychelants useful for complexing more than one paramagnetic metal ion for use in MRI contrast agents. U.S. 5,520,904, describes
5 particulate compositions comprised of paramagnetic metal ions for use as MRI contrast agents.

The pharmaceuticals of the present invention have the formulae, $(Q)_d-L_n-(C_h-X)$, $(Q)_d-L_n-(C_h-X^1)_d'$,
10 $(Q)_d-L_n-(X^2)_d''$, and $(Q)_d-L_n-(X^3)$, wherein Q represents a non-peptide that binds to a receptor expressed in angiogenic tumor vasculature, d is 1-10, L_n represents an optional linking group, C_h represents a metal chelator or bonding moiety, X represents a radioisotope, X^1
15 represents paramagnetic metal ion, X^2 represents a paramagnetic metal ion or heavy atom containing insoluble solid particle, d'' is 1-100, and X^3 represents a surfactant microsphere of an echogenic gas. The interaction of the non-peptide recognition sequences of
20 the vitronectin receptor binding portion of the pharmaceuticals with the $\alpha v\beta 3$ receptor results in localization of the pharmaceuticals in angiogenic tumor vasculature, which express the $\alpha v\beta 3$ receptor.

The pharmaceuticals of the present invention can be
25 synthesized by several approaches. One approach involves the synthesis of the targeting non-peptide moiety, Q, and direct attachment of one or more moieties, Q, to one or more metal chelators or bonding moieties, C_h , or to a paramagnetic metal ion or heavy atom containing solid
30 particle, or to an echogenic gas microbubble. Another approach involves the attachment of one or more moieties, Q, to the linking group, L_n , which is then attached to one or more metal chelators or bonding moieties, C_h , or

to a paramagnetic metal ion or heavy atom containing solid particle, or to an echogenic gas microbubble. Another approach involves the synthesis of a non-peptide, Q, bearing a fragment of the linking group, L_n , one or
5 more of which are then attached to the remainder of the linking group and then to one or more metal chelators or bonding moieties, C_h , or to a paramagnetic metal ion or heavy atom containing solid particle, or to an echogenic gas microbubble.

10 The non-peptide vitronectin binding moieties, Q, optionally bearing a linking group, L_n , or a fragment of the linking group, can be synthesized using standard synthetic methods known to those skilled in the art. Preferred methods include but are not limited to those
15 methods described below.

The attachment of linking groups, L_n , to the non-peptides, Q; chelators or bonding units, C_h , to the non-peptides, , Q, or to the linking groups, L_n ; and non-peptides, bearing a fragment of the linking group to the
20 remainder of the linking group, in combination forming the moiety, $(Q)_d-L_n$, and then to the moiety C_h ; can all be performed by standard techniques. These include, but are not limited to, amidation, esterification, alkylation, and the formation of ureas or thioureas. Procedures for
25 performing these attachments can be found in Brinkley, M., *Bioconjugate Chemistry* 1992, 3(1), which is incorporated herein by reference.

A number of methods can be used to attach the non-peptides, Q, to paramagnetic metal ion or heavy atom
30 containing solid particles, X^2 , by one of skill in the art of the surface modification of solid particles. In general, the targeting moiety Q or the combination $(Q)_dL_n$ is attached to a coupling group that react with a

constituent of the surface of the solid particle. The coupling groups can be any of a number of silanes which react with surface hydroxyl groups on the solid particle surface, as described in co-pending United States Patent
 5 Application Serial No. 09/356,178, and can also include polyphosphonates, polycarboxylates, polyphosphates or mixtures thereof which couple with the surface of the solid particles, as described in U.S. 5,520,904.

A number of reaction schemes can be used to attach
 10 the non-peptides, Q to the surfactant microsphere, X³. These are illustrated in following reaction schemes where S_f represents a surfactant moiety that forms the surfactant microsphere.

15 Acylation Reaction:

Y is a leaving group or active ester

20

Disulfide Coupling:

25 Sulfonamide Coupling:

30 Reductive Amidation:

In these reaction schemes, the substituents S_f and Q can be reversed as well.

The linking group L_n can serve several roles. First it provides a spacing group between the metal chelator or bonding moiety, C_h , the paramagnetic metal ion or heavy atom containing solid particle, X^2 , and the surfactant microsphere, X^3 , and the one or more of the non-peptides, Q, so as to minimize the possibility that the moieties C_h-X , C_h-X^1 , X^2 , and X^3 , will interfere with the interaction of the recognition sequences of Q with angiogenic tumor vasculature receptors. The necessity of incorporating a linking group in a reagent is dependent on the identity of Q, C_h-X , C_h-X^1 , X^2 , and X^3 . If C_h-X , C_h-X^1 , X^2 , and X^3 , cannot be attached to Q without substantially diminishing its affinity for the receptors, then a linking group is used. A linking group also provides a means of independently attaching multiple non-peptides, Q, to one group that is attached to C_h-X , C_h-X^1 , X^2 , or X^3 .

The linking group also provides a means of incorporating a pharmacokinetic modifier into the pharmaceuticals of the present invention. The pharmacokinetic modifier serves to direct the biodistribution of the injected pharmaceutical other than by the interaction of the targeting moieties, Q, with the vitronectin receptors expressed in the tumor neovasculature. A wide variety of functional groups can serve as pharmacokinetic modifiers, including, but not limited to, carbohydrates, polyalkylene glycols, peptides or other polyamino acids, and cyclodextrins. The modifiers can be used to enhance or decrease hydrophilicity and to enhance or decrease the rate of blood clearance. The modifiers can also be used to

direct the route of elimination of the pharmaceuticals. Preferred pharmacokinetic modifiers are those that result in moderate to fast blood clearance and enhanced renal excretion.

5 The metal chelator or bonding moiety, C_h , is selected to form stable complexes with the metal ion chosen for the particular application. Chelators or bonding moieties for diagnostic radiopharmaceuticals are selected to form stable complexes with the radioisotopes
10 that have imageable gamma ray or positron emissions, such as ^{99m}Tc , ^{95}Tc , ^{111}In , ^{62}Cu , ^{60}Cu , ^{64}Cu , ^{67}Ga , ^{68}Ga , ^{86}Y .

Chelators for technetium, copper and gallium isotopes are selected from diaminedithiols, monoamine-monoamidedithiols, triamide-monothiols,
15 monoamine-diamide-monothiols, diaminedioximes, and hydrazines. The chelators are generally tetradentate with donor atoms selected from nitrogen, oxygen and sulfur. Preferred reagents are comprised of chelators having amine nitrogen and thiol sulfur donor atoms and
20 hydrazine bonding units. The thiol sulfur atoms and the hydrazines may bear a protecting group which can be displaced either prior to using the reagent to synthesize a radiopharmaceutical or preferably in situ during the synthesis of the radiopharmaceutical.

25 Exemplary thiol protecting groups include those listed in Greene and Wuts, "Protective Groups in Organic Synthesis" John Wiley & Sons, New York (1991), the disclosure of which is hereby incorporated by reference. Any thiol protecting group known in the art can be used.
30 Examples of thiol protecting groups include, but are not limited to, the following: acetamidomethyl, benzamidomethyl, 1-ethoxyethyl, benzoyl, and triphenylmethyl.

Exemplary protecting groups for hydrazine bonding units are hydrazones which can be aldehyde or ketone hydrazones having substituents selected from hydrogen, alkyl, aryl and heterocycle. Particularly preferred
5 hydrazones are described in co-pending U.S.S.N. 08/476,296 the disclosure of which is herein incorporated by reference in its entirety.

The hydrazine bonding unit when bound to a metal radionuclide is termed a hydrazido, or diazenido group
10 and serves as the point of attachment of the radionuclide to the remainder of the radiopharmaceutical. A diazenido group can be either terminal (only one atom of the group is bound to the radionuclide) or chelating. In order to have a chelating diazenido group at least one other atom
15 of the group must also be bound to the radionuclide. The atoms bound to the metal are termed donor atoms.

Chelators for ^{111}In and ^{86}Y are selected from cyclic and acyclic polyaminocarboxylates such as DTPA, DOTA, DO3A, 2-benzyl-DOTA, alpha-(2-phenethyl)1,4,7,10-
20 tetraazacyclododecane-1-acetic-4,7,10-tris(methylacetic)acid, 2-benzyl-cyclohexyldiethylenetriaminepentaacetic acid, 2-benzyl-6-methyl-DTPA, and 6,6"-bis[N,N,N",N"-tetra(carboxymethyl)aminomethyl)-4'-(3-amino-4-methoxyphenyl)-2,2':6',2"-terpyridine. Procedures for
25 synthesizing these chelators that are not commercially available can be found in Brechbiel, M. and Gansow, O., *J. Chem. Soc. Perkin Trans. 1992, 1, 1175*; Brechbiel, M. and Gansow, O., *Bioconjugate Chem. 1991, 2, 187*;
30 Deshpande, S., et. al., *J. Nucl. Med. 1990, 31, 473*; Kruper, J., U.S. Patent 5,064,956, and Toner, J., U.S. Patent 4,859,777, the disclosures of which are hereby incorporated by reference in their entirety.

The coordination sphere of metal ion includes all the ligands or groups bound to the metal. For a transition metal radionuclide to be stable it typically has a coordination number (number of donor atoms) 5 comprised of an integer greater than or equal to 4 and less than or equal to 8; that is there are 4 to 8 atoms bound to the metal and it is said to have a complete coordination sphere. The requisite coordination number for a stable radionuclide complex is determined by the 10 identity of the radionuclide, its oxidation state, and the type of donor atoms. If the chelator or bonding unit does not provide all of the atoms necessary to stabilize the metal radionuclide by completing its coordination sphere, the coordination sphere is completed by donor 15 atoms from other ligands, termed ancillary or co-ligands, which can also be either terminal or chelating.

A large number of ligands can serve as ancillary or co-ligands, the choice of which is determined by a variety of considerations such as the ease of synthesis 20 of the radiopharmaceutical, the chemical and physical properties of the ancillary ligand, the rate of formation, the yield, and the number of isomeric forms of the resulting radiopharmaceuticals, the ability to administer said ancillary or co-ligand to a patient 25 without adverse physiological consequences to said patient, and the compatibility of the ligand in a lyophilized kit formulation. The charge and lipophilicity of the ancillary ligand will effect the charge and lipophilicity of the radiopharmaceuticals. 30 For example, the use of 4,5-dihydroxy-1,3-benzene disulfonate results in radiopharmaceuticals with an additional two anionic groups because the sulfonate groups will be anionic under physiological conditions. The use of N-alkyl substituted 3,4-hydroxypyridinones

results in radiopharmaceuticals with varying degrees of lipophilicity depending on the size of the alkyl substituents.

Preferred technetium radiopharmaceuticals of the present invention are comprised of a hydrazido or diazenido bonding unit and an ancillary ligand, A_{L1} , or a bonding unit and two types of ancillary A_{L1} and A_{L2} , or a tetradentate chelator comprised of two nitrogen and two sulfur atoms. Ancillary ligands A_{L1} are comprised of two or more hard donor atoms such as oxygen and amine nitrogen (sp^3 hybridized). The donor atoms occupy at least two of the sites in the coordination sphere of the radionuclide metal; the ancillary ligand A_{L1} serves as one of the three ligands in the ternary ligand system. Examples of ancillary ligands A_{L1} include but are not limited to dioxygen ligands and functionalized aminocarboxylates. A large number of such ligands are available from commercial sources.

Ancillary dioxygen ligands include ligands that coordinate to the metal ion through at least two oxygen donor atoms. Examples include but are not limited to: glucoheptonate, gluconate, 2-hydroxyisobutyrate, lactate, tartrate, mannitol, glucarate, maltol, Kojic acid, 2,2-bis(hydroxymethyl)propionic acid, 4,5-dihydroxy-1,3-benzene disulfonate, or substituted or unsubstituted 1,2 or 3,4 hydroxypyridinones. (The names for the ligands in these examples refer to either the protonated or non-protonated forms of the ligands.)

Functionalized aminocarboxylates include ligands that have a combination of amine nitrogen and oxygen donor atoms. Examples include but are not limited to: iminodiacetic acid, 2,3-diaminopropionic acid, nitrilotriacetic acid, N,N'-ethylenediamine diacetic acid, N,N,N'-ethylenediamine triacetic acid,

hydroxyethylethylenediamine triacetic acid, and N,N'-ethylenediamine bis-hydroxyphenylglycine. (The names for the ligands in these examples refer to either the protonated or non-protonated forms of the ligands.)

5 A series of functionalized aminocarboxylates are disclosed by Bridger et. al. in U.S. Patent 5,350,837, herein incorporated by reference, that result in improved rates of formation of technetium labeled hydrazino modified proteins. We have determined that certain of
10 these aminocarboxylates result in improved yields of the radiopharmaceuticals of the present invention. The preferred ancillary ligands A_{L1} functionalized aminocarboxylates that are derivatives of glycine; the most preferred is tricine
15 (tris(hydroxymethyl)methylglycine).

The most preferred technetium radiopharmaceuticals of the present invention are comprised of a hydrazido or diazenido bonding unit and two types of ancillary designated A_{L1} and A_{L2} , or a diaminedithiol chelator. The
20 second type of ancillary ligands A_{L2} are comprised of one or more soft donor atoms selected from the group: phosphine phosphorus, arsine arsenic, imine nitrogen (sp^2 hybridized), sulfur (sp^2 hybridized) and carbon (sp hybridized); atoms which have p-acid character. Ligands
25 A_{L2} can be monodentate, bidentate or tridentate, the denticity is defined by the number of donor atoms in the ligand. One of the two donor atoms in a bidentate ligand and one of the three donor atoms in a tridentate ligand must be a soft donor atom. We have disclosed in
30 co-pending U.S.S.N. 08/415,908, and U.S.S.N. 60/013360 and 08/646,886, the disclosures of which are herein incorporated by reference in their entirety, that radiopharmaceuticals comprised of one or more ancillary or co-ligands A_{L2} are more stable compared to

radiopharmaceuticals that are not comprised of one or more ancillary ligands, A_{L2} ; that is, they have a minimal number of isomeric forms, the relative ratios of which do not change significantly with time, and that remain
5 substantially intact upon dilution.

The ligands A_{L2} that are comprised of phosphine or arsine donor atoms are trisubstituted phosphines, trisubstituted arsines, tetrasubstituted diphosphines and tetrasubstituted diarsines. The ligands A_{L2} that are
10 comprised of imine nitrogen are unsaturated or aromatic nitrogen-containing, 5 or 6-membered heterocycles. The ligands that are comprised of sulfur (sp^2 hybridized) donor atoms are thiocarbonyls, comprised of the moiety $C=S$. The ligands comprised of carbon (sp hybridized)
15 donor atoms are isonitriles, comprised of the moiety CNR , where R is an organic radical. A large number of such ligands are available from commercial sources. Isonitriles can be synthesized as described in European Patent 0107734 and in U.S. Patent 4,988,827, herein
20 incorporated by reference.

Preferred ancillary ligands A_{L2} are trisubstituted phosphines and unsaturated or aromatic 5 or 6 membered heterocycles. The most preferred ancillary ligands A_{L2} are trisubstituted phosphines and unsaturated 5 membered
25 heterocycles.

The ancillary ligands A_{L2} may be substituted with alkyl, aryl, alkoxy, heterocycle, aralkyl, alkaryl and arylalkaryl groups and may or may not bear functional groups comprised of heteroatoms such as oxygen, nitrogen,
30 phosphorus or sulfur. Examples of such functional groups include but are not limited to: hydroxyl, carboxyl, carboxamide, nitro, ether, ketone, amino, ammonium, sulfonate, sulfonamide, phosphonate, and phosphonamide. The functional groups may be chosen to alter the

lipophilicity and water solubility of the ligands which may affect the biological properties of the radiopharmaceuticals, such as altering the distribution into non-target tissues, cells or fluids, and the
5 mechanism and rate of elimination from the body.

Chelators or bonding moieties for therapeutic radiopharmaceuticals are selected to form stable complexes with the radioisotopes that have alpha particle, beta particle, Auger or Coster-Kronig electron

- 5 The technetium and rhenium radiopharmaceuticals of the present invention comprised of a hydrazido or diazenido bonding unit can be easily prepared by admixing a salt of a radionuclide, a reagent of the present invention, an ancillary ligand A_{L1} , an ancillary ligand
- 10 A_{L2} , and a reducing agent, in an aqueous solution at temperatures from 0 to 100 °C. The technetium and rhenium radiopharmaceuticals of the present invention comprised of a tetradentate chelator having two nitrogen and two sulfur atoms can be easily prepared by admixing a
- 15 salt of a radionuclide, a reagent of the present invention, and a reducing agent, in an aqueous solution at temperatures from 0 to 100 °C.

- When the bonding unit in the reagent of the present invention is present as a hydrazone group, then it must
- 20 first be converted to a hydrazine, which may or may not be protonated, prior to complexation with the metal radionuclide. The conversion of the hydrazone group to the hydrazine can occur either prior to reaction with the radionuclide, in which case the radionuclide and the
- 25 ancillary or co-ligand or ligands are combined not with the reagent but with a hydrolyzed form of the reagent bearing the chelator or bonding unit, or in the presence of the radionuclide in which case the reagent itself is combined with the radionuclide and the ancillary or
- 30 co-ligand or ligands. In the latter case, the pH of the reaction mixture must be neutral or acidic.

Alternatively, the radiopharmaceuticals of the present invention comprised of a hydrazido or diazenido bonding unit can be prepared by first admixing a salt of

a radionuclide, an ancillary ligand A_{L1} , and a reducing agent in an aqueous solution at temperatures from 0 to 100 °C to form an intermediate radionuclide complex with the ancillary ligand A_{L1} then adding a reagent of the present invention and an ancillary ligand A_{L2} and reacting further at temperatures from 0 to 100°C.

Alternatively, the radiopharmaceuticals of the present invention comprised of a hydrazido or diazenido bonding unit can be prepared by first admixing a salt of a radionuclide, an ancillary ligand A_{L1} , a reagent of the present invention, and a reducing agent in an aqueous solution at temperatures from 0 to 100°C to form an intermediate radionuclide complex, and then adding an ancillary ligand A_{L2} and reacting further at temperatures from 0 to 100°C.

The technetium and rhenium radionuclides are preferably in the chemical form of pertechnetate or perrhenate and a pharmaceutically acceptable cation. The pertechnetate salt form is preferably sodium pertechnetate such as obtained from commercial Tc-99m generators. The amount of pertechnetate used to prepare the radiopharmaceuticals of the present invention can range from 0.1 mCi to 1 Ci, or more preferably from 1 to 200 mCi.

The amount of the reagent of the present invention used to prepare the technetium and rhenium radiopharmaceuticals of the present invention can range from 0.01 µg to 10 mg, or more preferably from 0.5 µg to 200 µg. The amount used will be dictated by the amounts of the other reactants and the identity of the radiopharmaceuticals of the present invention to be prepared.

The amounts of the ancillary ligands A_{L1} used can range from 0.1 mg to 1 g, or more preferably from 1 mg to

100 mg. The exact amount for a particular radiopharmaceutical is a function of identity of the radiopharmaceuticals of the present invention to be prepared, the procedure used and the amounts and
5 identities of the other reactants. Too large an amount of A_{L1} will result in the formation of by-products comprised of technetium labeled A_{L1} without a biologically active molecule or by-products comprised of technetium labeled biologically active molecules with the ancillary
10 ligand A_{L1} but without the ancillary ligand A_{L2} . Too small an amount of A_{L1} will result in other by-products such as technetium labeled biologically active molecules with the ancillary ligand A_{L2} but without the ancillary ligand A_{L1} , or reduced hydrolyzed technetium, or
15 technetium colloid.

The amounts of the ancillary ligands A_{L2} used can range from 0.001 mg to 1 g, or more preferably from 0.01 mg to 10 mg. The exact amount for a particular radiopharmaceutical is a function of the identity of the
20 radiopharmaceuticals of the present invention to be prepared, the procedure used and the amounts and identities of the other reactants. Too large an amount of A_{L2} will result in the formation of by-products comprised of technetium labeled A_{L2} without a biologically
25 active molecule or by-products comprised of technetium labeled biologically active molecules with the ancillary ligand A_{L2} but without the ancillary ligand A_{L1} . If the reagent bears one or more substituents that are comprised of a soft donor atom, as defined above, at least a
30 ten-fold molar excess of the ancillary ligand A_{L2} to the reagent of formula 2 is required to prevent the substituent from interfering with the coordination of the ancillary ligand A_{L2} to the metal radionuclide.

Suitable reducing agents for the synthesis of the radiopharmaceuticals of the present invention include stannous salts, dithionite or bisulfite salts, borohydride salts, and formamidinesulfinic acid, wherein
5 the salts are of any pharmaceutically acceptable form. The preferred reducing agent is a stannous salt. The amount of a reducing agent used can range from 0.001 mg to 10 mg, or more preferably from 0.005 mg to 1 mg.

The specific structure of a radiopharmaceutical of
10 the present invention comprised of a hydrazido or diazenido bonding unit will depend on the identity of the reagent of the present invention used, the identity of any ancillary ligand A_{L1} , the identity of any ancillary ligand A_{L2} , and the identity of the radionuclide.
15 Radiopharmaceuticals comprised of a hydrazido or diazenido bonding unit synthesized using concentrations of reagents of $<100 \mu\text{g/mL}$, will be comprised of one hydrazido or diazenido group. Those synthesized using $>1 \text{ mg/mL}$ concentrations will be comprised of two hydrazido
20 or diazenido groups from two reagent molecules. For most applications, only a limited amount of the biologically active molecule can be injected and not result in undesired side-effects, such as chemical toxicity, interference with a biological process or an altered
25 biodistribution of the radiopharmaceutical. Therefore, the radiopharmaceuticals which require higher concentrations of the reagents comprised in part of the biologically active molecule, will have to be diluted or purified after synthesis to avoid such side-effects.

30 The identities and amounts used of the ancillary ligands A_{L1} and A_{L2} will determine the values of the variables y and z . The values of y and z can independently be an integer from 1 to 2. In combination, the values of y and z will result in a technetium

coordination sphere that is made up of at least five and no more than seven donor atoms. For monodentate ancillary ligands AL_2 , z can be an integer from 1 to 2; for bidentate or tridentate ancillary ligands AL_2 , z is 1.

- 5 The preferred combination for monodentate ligands is y equal to 1 or 2 and z equal to 1. The preferred combination for bidentate or tridentate ligands is y equal to 1 and z equal to 1.

The indium, copper, gallium, silver, palladium,
10 rhodium, gold, platinum, bismuth, yttrium and lanthanide radiopharmaceuticals of the present invention can be easily prepared by admixing a salt of a radionuclide and a reagent of the present invention, in an aqueous solution at temperatures from 0 to 100°C. These
15 radionuclides are typically obtained as a dilute aqueous solution in a mineral acid, such as hydrochloric, nitric or sulfuric acid. The radionuclides are combined with from one to about one thousand equivalents of the reagents of the present invention dissolved in aqueous
20 solution. A buffer is typically used to maintain the pH of the reaction mixture between 3 and 10.

The gadolinium, dysprosium, iron and manganese metallopharmaceuticals of the present invention can be easily prepared by admixing a salt of the paramagnetic
25 metal ion and a reagent of the present invention, in an aqueous solution at temperatures from 0 to 100 °C. These paramagnetic metal ions are typically obtained as a dilute aqueous solution in a mineral acid, such as hydrochloric, nitric or sulfuric acid. The paramagnetic
30 metal ions are combined with from one to about one thousand equivalents of the reagents of the present invention dissolved in aqueous solution. A buffer is typically used to maintain the pH of the reaction mixture between 3 and 10.

The total time of preparation will vary depending on the identity of the metal ion, the identities and amounts of the reactants and the procedure used for the preparation. The preparations may be complete, resulting
5 in > 80% yield of the radiopharmaceutical, in 1 minute or may require more time. If higher purity metallopharmaceuticals are needed or desired, the products can be purified by any of a number of techniques well known to those skilled in the art such as liquid
10 chromatography, solid phase extraction, solvent extraction, dialysis or ultrafiltration.

10 than one function. A reducing agent can also serve as a stabilization aid, a buffer can also serve as a transfer ligand, a lyophilization aid can also serve as a transfer, ancillary or co-ligand and so forth.

The following procedure describe the synthesis of radiopharmaceuticals of the present invention of the formula $^{99m}\text{Tc}(\text{VnA})(\text{tricine})(\text{phosphine})$, in which (VnA) represents a vitronectin receptor antagonist compound of the present invention bonded to the Tc through a diazenido ($=\text{N}=\text{N}-$) or hydrazido ($=\text{N}-\text{NH}-$) moiety. The

25

diazenido or hydrazido moiety results from the reaction of the hydrazinonicotinamido group, present either as the free hydrazine or protected as a hydrazone, with the Tc-99m. The other two ligands in the Tc coordination sphere are tricine and a phosphine.

Ethyl 1H-indazole-5-carboxylate (1.5 g, 7.9 mmol) and 18-crown-6 (45 mg) were added to dry THF (45 mL) in flame-dried glassware under nitrogen. Sodium bis(trimethylsilyl)amide (8.7 mL of 1M solution in THF, 8.7 mmol) was added via syringe, followed by N-(2-bromoethyl)phthalimide (2.5 g, 9.8 mmol). The reaction was heated at reflux temperature for 22 hr, cooled, and concentrated under vacuum. The residue was partitioned between toluene and water, separated, and the aqueous

layer extracted with ethyl acetate. The combined organics were washed with water and brine, dried over sodium sulfate, filtered and concentrated to afford 3.5 g of an oil. This was purified by flash chromatography (toluene - ethyl acetate gradient), collecting two separate products which were concentrated to yield the products as oils which solidified on standing. The 1-substituted indazole eluted first (980 mg), followed by the 2-substituted analog (600 mg) for a combined yield of 55%. Their mass spectra were identical. LRMS (ES): 364.1 ($[M + H]^+$, 100%), 386.1 ($[M + Na]^+$, 15%)

Hydrazine (365 uL) was added and the reaction stirred 17 hours. THF (75 mL) was added and the resulting solids were filtered off. The filtrate was concentrated to an orange solid, which was purified by flash chromatography (dichloromethane/5% methanol/0.5% triethylamine).  cyclododecyl]acetyl}amino)ethyl]amino)sulfonyl}phenyl)phen
 yl)sulfonyl)amino)propanoic acid

Step A: Synthesis of methyl 3-formyl-1-methyl-1H-indazole-6-carboxylate

5

In a dry flask under nitrogen is added dry DMF (1.6 mL) and the solution cooled to -5C in an ice/ethanol bath. Phosphorous oxychloride (530 uL, 5.7 mmol) is added via syringe and the solution is allowed to stir for 30 minutes in the bath. Methyl 1-methyl-1H-indazole-6-carboxylate, (500 mg, 2.84 mmol, prepared as in Jadhav et al, US patent 5,760,028) dissolved in DMF (3 mL) is added slowly to the cold solution. The reaction is then warmed to 35C, stirred for four hours, and then poured onto crushed ice. The resulting slurry is neutralized with 1N NaOH to pH = 7, heated rapidly to boiling for 1 minute, cooled quickly to room temperature, and the solution extracted with ethyl acetate. The combined organics are washed with water and brine, dried, filtered and concentrated. The resulting oil is purified by flash chromatography to afford the product.

Step B: Synthesis of methyl 1-methyl-3-(((1-(triphenylmethyl)imidazol-2-yl)amino)methyl)-1H-indazole-6-carboxylate

25

The product of Step A (204 mg, 1 mmol) is dissolved in toluene (10 mL) with N-trityl-2-aminoimidazole (357 mg, 1.1 mmol) and heated to reflux with a Dean-Stark trap. Four aliquots of toluene (3 mL each) are removed via distillation at 1.5 hour intervals, being replaced by dry toluene each time, and then the solution is left to reflux for 18 hours. The reaction is cooled to room temperature and sodium triacetoxyborohydride (1 gram, 5 mmol) is added in one portion. The reaction is stirred at room temperature for 24 hours, poured into water, and the layers separated. The aqueous layer is extracted with ethyl acetate and the combined organic layers are washed with saturated bicarbonate, water, and brine, dried over magnesium sulfate, concentrated, and purified by flash chromatography to afford the product.

Step C: Synthesis of 1-((1-(triphenylmethyl)imidazol-2-yl)amino)methyl)-1H-indazole-5-carboxylic acid

The product of Step B (250 mg, 474 umol) is added to THF/water (1:1, 15 mL) along with lithium hydroxide (3N, 0.8 mL, 2.4 mmol) and the solution stirred, following by TLC until the starting material has disappeared, when the THF is removed under vacuum. The reaction is acidified to pH = 2 with 1N HCl and the resulting solids are

filtered, washed with water, and dried under vacuum to afford the product.

Step D: Synthesis of

5

The product of Step C (190 mg, 370 μmol) is reacted with the product of Example 44, Step A (285 mg, 407 μmol) as in Example 44, Step B and the residue is purified by preparative HPLC (Vydac C-18, 21.2 mm x 25 cm, 90%

10 acetonitrile/water/ 0.1% trifluoroacetic acid; 10-70% B over 30 minutes). The product fractions are combined, frozen, and lyophilized to afford the product.

Step E: Synthesis of methyl (2S)-2-(((4-(4-(((2-aminoethyl)amino)sulfonyl)phenyl)phenyl)sulfonyl)amino)-3-([1-methyl-3-([1-(triphenylmethyl)imidazol-2-yl]amino)methyl) (1H-indazol-6-yl)]carbonylamino)propanoate

15

20 The product of Step D (100 mg) in methanol (10 mL) is added to a slurry of 10% palladium on carbon (50 mg) in methanol (8 mL) in a Parr bottle under nitrogen. The solution is hydrogenated at 50 psi for 1.5 hours,

filtered through Celite, washed with methanol, and the combined filtrates concentrated. The resulting oil is not purified but carried directly into the next step.

- 5 Step F: Synthesis of methyl (2S)-3-([1-methyl-3-([1-(triphenylmethyl)imidazol-2-yl]amino)methyl](1H-indazol-6-yl)]carbonylamino)-2-([(4-{4-[(2-[2-(1,4,7,10-tetraaza-4,7,10-tris([(tert-butyl)oxycarbonyl]methyl)cyclododecyl)acetyl
- 10 amino]ethyl)amino)sulfonyl]phenyl)phenyl)sulfonyl]amino)propanoate

- The product of Step E (73 mg, 77 umol) is reacted with DOTA(OtBu)₃-OH (49 mg, 85 umol) as in Example 37, Step F,
- 15 to afford the product as a pure compound after purification and lyophilization.

- Step G: Synthesis of (2S)-3-([3-[(imidazol-2-ylamino)methyl]-1-methyl(1H-indazol-6-yl)]carbonylamino)-2-([(4-{4-[(2-[2-[1,4,7,10-tetraaza-4,7,10-tris(carboxymethyl)cyclododecyl]acetyl
- 20 amino]ethyl)amino]sulfonyl]phenyl)phenyl)sulfonyl]amino)propanoic acid

The product of Step F (73 mg, 77 umol) is deprotected as in Example 40, Step J, to afford the product as a pure compound after preparative HPLC purification and lyophilization of the product fractions.

Utility

The pharmaceuticals of the present invention are useful for imaging angiogenic tumor vasculature, therapeutic cardiovascular angiogenesis, and cardiac pathologies associated with the expression of vitronectin receptors in a patient or for treating cancer in a patient. The radiopharmaceuticals of the present invention comprised of a gamma ray or positron emitting isotope are useful for imaging of pathological processes involving angiogenic neovasculature, including cancer, diabetic retinopathy, macular degeneration, restenosis of blood vessels after angioplasty, and wound healing, as well as atherosclerotic plaque, myocardial reperfusion injury, and myocardial ischemia, stunning or infarction. The radiopharmaceuticals of the present invention comprised of a beta, alpha or Auger electron emitting isotope are useful for treatment of pathological processes involving angiogenic neovasculature, by delivering a cytotoxic dose of radiation to the locus of the angiogenic neovasculature. The treatment of cancer is affected by the systemic administration of the radiopharmaceuticals resulting in a cytotoxic radiation dose to tumors.

The compounds of the present invention comprised of one or more paramagnetic metal ions selected from gadolinium, dysprosium, iron, and manganese, are useful as contrast agents for magnetic resonance imaging (MRI) of pathological processes involving angiogenic neovasculature, as well as atherosclerotic plaque,

myocardial reperfusion injury, and myocardial ischemia, stunning or infarction.

The compounds of the present invention comprised of one or more heavy atoms with atomic number of 20 or greater are useful as X-ray contrast agents for X-ray imaging of pathological processes involving angiogenic neovasculature, as well as atherosclerotic plaque, myocardial reperfusion injury, and myocardial ischemia, stunning or infarction.

The compounds of the present invention comprised of an echogenic gas containing surfactant microsphere are useful as ultrasound contrast agents for sonography of pathological processes involving angiogenic neovasculature, as well as atherosclerotic plaque, myocardial reperfusion injury, and myocardial ischemia, stunning or infarction.

Representative compounds of the present invention were tested in the following in vitro assays and in vivo models and were found to be active.

Immobilized Human Placental $\alpha_v\beta_3$ Receptor Assay

The assay conditions were developed and validated using [I-125]vitronectin. Assay validation included Scatchard format analysis (n=3) where receptor number (Bmax) and Kd (affinity) were determined. Assay format is such that compounds are preliminarily screened at 10 and 100 nM final concentrations prior to IC50 determination. Three standards (vitronectin, anti- $\alpha_v\beta_3$ antibody, LM609, and anti-avB5, PlF6) and five reference peptides have been evaluated for IC50 determination. Briefly, the method involves immobilizing previously isolated receptors in 96 well plates and incubating overnight. The receptors were isolated from normal, fresh, non-infectious (HIV, hepatitis B and C, syphilis,

and HTLV free) human placenta. The tissue was lysed and tissue debris removed via centrifugation. The lysate was filtered. The receptors were isolated by affinity chromatography using the immobilized $\alpha_v\beta_3$ antibody. The
5 plates are then washed 3x with wash buffer. Blocking buffer is added and plates incubated for 120 minutes at room temperature. During this time compounds to be tested and [I-125]vitronectin are premixed in a reservoir plate. Blocking buffer is removed and compound mixture
10 pipetted. Competition is carried out for 60 minutes at room temperature. Unbound material is then removed and wells are separated and counted via gamma scintillation.

Oncomouse® Imaging

15 The study involves the use of the c-Neu Oncomouse® and FVB mice simultaneously as controls. The mice are anesthetized with sodium pentobarbital and injected with approximately 0.5 mCi of radiopharmaceutical. Prior to injection, the tumor locations on each Oncomouse® are
20 recorded and tumor size measured using calipers. The animals are positioned on the camera head so as to image the anterior or posterior of the animals. 5 Minute dynamic images are acquired serially over 2 hours using a 256x256 matrix and a zoom of 2x. Upon completion of the
25 study, the images are evaluated by circumscribing the tumor as the target region of interest (ROI) and a background site in the neck area below the carotid salivary glands.

This model can also be used to assess the
30 effectiveness of the radiopharmaceuticals of the present invention comprised of a beta, alpha or Auger electron emitting isotope. The radiopharmaceuticals are administered in appropriate amounts and the uptake in the tumors can be quantified either non-invasively by imaging

for those isotopes with a coincident imageable gamma emission, or by excision of the tumors and counting the amount of radioactivity present by standard techniques. The therapeutic effect of the radiopharmaceuticals can be
5 assessed by monitoring the rate of growth of the tumors in control mice versus those in the mice administered the radiopharmaceuticals of the present invention.

This model can also be used to assess the compounds of the present invention comprised of paramagnetic metals

Rabbit Matrigel Model

This model was adapted from a matrigel model intended for the study of angiogenesis in mice. Matrigel (Becton & Dickinson, USA) is a basement membrane rich in laminin, collagen IV, entactin, HSPG and other growth factors. When combined with growth factors such as bFGF [500 ng/ml] or VEGF [2 µg/ml] and injected subcutaneously into the mid-abdominal region of the mice, it solidifies into a gel and stimulates angiogenesis at the site of injection within 4-8 days. In the rabbit model, New Zealand White rabbits (2.5-3.0 kg) are injected with 2.0 ml of matrigel, plus 1 µg bFGF and 4 µg VEGF. The radiopharmaceutical is then injected 7 days later and the images obtained.

This model can also be used to assess the effectiveness of the radiopharmaceuticals of the present invention comprised of a beta, alpha or Auger electron emitting isotope. The radiopharmaceuticals are administered in appropriate amounts and the uptake at the angiogenic sites can be quantified either non-invasively by imaging for those isotopes with a coincident imageable gamma emission, or by excision of the angiogenic sites and counting the amount of radioactivity present by standard techniques. The therapeutic effect of the radiopharmaceuticals can be assessed by monitoring the rate of growth of the angiogenic sites in control rabbits versus those in the rabbits administered the radiopharmaceuticals of the present invention.

This model can also be used to assess the compounds of the present invention comprised of paramagnetic metals as MRI contrast agents. After administration of the appropriate amount of the paramagnetic compounds, the whole animal can be placed in a commercially available

magnetic resonance imager to image the angiogenic sites. The effectiveness of the contrast agents can be readily seen by comparison to the images obtain from animals that are not administered a contrast agent.

25 **Canine Spontaneous Tumor Model**

Adult dogs with spontaneous mammary tumors were sedated with xylazine (20 mg/kg)/atropine (1 ml/kg). Upon sedation the animals were intubated using ketamine (5 mg/kg)/diazepam (0.25 mg/kg) for full anesthesia. Chemical restraint was continued with ketamine (3 mg/kg)/xylazine (6 mg/kg) titrating as necessary. If required the animals were ventilated with room air via an endotracheal tube (12 strokes/min, 25 ml/kg) during the study. Peripheral veins were catheterized using 20G I.V.

catheters, one to serve as an infusion port for compound while the other for exfusion of blood samples. Heart rate and EKG were monitored using a cardiometer (Biotech, Grass Quincy, MA) triggered from a lead II
5 electrocardiogram generated by limb leads. Blood samples are generally taken at ~10 minutes (control), end of infusion, (1 minute), 15 min, 30 min, 60 min, 90 min, and 120 min for whole blood cell number and counting. Radiopharmaceutical dose was 300 $\mu\text{Ci}/\text{kg}$ administered as an
10 i.v. bolus with saline flush. Parameters were monitored continuously on a polygraph recorder (Model 7E Grass) at a paper speed of 10 mm/min or 10 mm/sec.

Imaging of the laterals were for 2 hours with a 256x256 matrix, no zoom, 5 minute dynamic images. A
15 known source is placed in the image field (20-90 μCi) to evaluate region of interest (ROI) uptake. Images were also acquired 24 hours post injection to determine retention of the compound in the tumor. The uptake is determined by taking the fraction of the total counts in
20 an inscribed area for ROI/source and multiplying the known μCi . The result is μCi for the ROI.

This model can also be used to assess the effectiveness of the radiopharmaceuticals of the present invention comprised of a beta, alpha or Auger electron
25 emitting isotope. The radiopharmaceuticals are administered in appropriate amounts and the uptake in the tumors can be quantified either non-invasively by imaging for those isotopes with a coincident imageable gamma emission, or by excision of the tumors and counting the
30 amount of radioactivity present by standard techniques. The therapeutic effect of the radiopharmaceuticals can be assessed by monitoring the size of the tumors over time.

This model can also be used to assess the compounds of the present invention comprised of paramagnetic metals

The effectiveness of the contrast agents can be readily seen by comparison to the images obtain from animals that are not administered a contrast agent.

Cardiovascular disease models that can be used to assess the diagnostic radiopharmaceuticals, magnetic resonance, X-ray and ultrasound contrast agents of the present invention are reviewed in J. Nucl. Cardiol., 1998, 5, 167-83. There are several well established rabbit models of atherosclerosis; one model produces predominantly proliferating smooth muscle cells by balloon deendothelialization of infradiaphragmatic abdominal aorta to simulate restenotic lesions; another

model that produces simulated advanced human atherosclerotic plaque by balloon deendothelialization followed by a high cholesterol diet.

5 A model of congestive heart failure is described in Am. J. Physiol., 1998, 274, H1516-23. In general, Yorkshire pigs are randomly assigned to undergo 3 wks of rapid atrial pacing at 240 beats/min. or to be sham controls. The pigs are chronically instrumented to measure left ventricular function in the conscious state.
10 The pigs are anesthetized. A shielded stimulating electrode is sutured onto the left atrium, connected to a modified programmable pace maker and buried in a subcutaneous pocket. The pericardium is closed loosely, the thoracotomy is closed, and the
15 pleural space is evacuated of air. After a recovery period of 7-10 days, the pacemaker is activated in the animals selected to undergo chronic rapid pacing. The animals are sedated, the pacemaker is deactivated (pacing groups only. After a 30 min stabilization period,
20 indexes of LV function and geometry are determined (by echocardiography as a control) by injecting the radiolabeled compound. For biodistribution, the animals are anesthetized, the heart extirpate and the LV apex and midventricular regions are evaluated.

25 A rat model of reversible coronary occlusion and reperfusion is described in McNulty et al., J. Am. Physiol., 1996, H2283-9.

Obviously, numerous modifications and variations of the present invention are possible in light of the above
30 teachings. It is therefore to be understood that within the scope of the appended claims, the invention may be practiced otherwise than as specifically described herein.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

Continuation of Box I.1

Although claims 31-33 are directed to a method of treatment of the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition.

Although claims 34-41, 50-55 are directed to a diagnostic method practised on the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition.

Continuation of Box I.2

Claims Nos.: 1-5, 7-15, 17, 19-22, 24, 26-28, 30-45, 46-57

Present claims 1-57 relate to compounds/kits defined by reference to desirable characteristics or properties, namely "receptor that is upregulated during angiogenesis", "targeting moiety", "chelator", "linking groups", "indazole nonpeptide" "a surfactant"

The claims cover all compounds/kits having these characteristics or properties, whereas the application provides support within the meaning of Article 6 PCT and/or disclosure within the meaning of Article 5 PCT for only a very limited number of such compounds/kits. In the present case, the claims so lack support, and the application so lacks disclosure, that a meaningful search over the whole of the claimed scope is impossible. Independent of the above reasoning, the claims also lack clarity (Article 6 PCT). An attempt is made to define the compounds by reference to a result to be achieved. Again, this lack of clarity in the present case is such as to render a meaningful search over the whole of the claimed scope impossible.

Moreover claims 1-5, 7-15, 17, 19-22, 24, 26-28, 30-45, 46-57 relate to an extremely large number of possible compounds/kits. Support within the meaning of Article 6 PCT and/or disclosure within the meaning of Article 5 PCT is to be found, however, for only a very small proportion of the compounds/kits claimed. In the present case, the claims so lack support, and the application so lacks disclosure, that a meaningful search over the whole of the claimed scope is impossible. Consequently, the search has been carried out for those parts of the claims which appear to be supported and disclosed, namely those parts relating to the compounds/products/apparatus/methods

Consequently, the search has been carried out for those parts of the claims which appear to be clear, supported and disclosed, namely those parts relating to the compounds/kits prepared in the examples and specifically mentioned by name in the claims with due regard to the general idea underlying the present application

The applicant's attention is drawn to the fact that claims, or parts of claims, relating to inventions in respect of which no international search report has been established need not be the subject of an international preliminary examination (Rule 66.1(e) PCT). The applicant is advised that the EPO policy when acting as an International Preliminary Examining Authority is normally not to carry out a preliminary examination on matter which has not been searched. This is the case irrespective of whether or not the claims are amended following receipt of the search report or during any Chapter II procedure.
